Implementation Techniques: Classification

- Decompositional Approaches
  - Text-based filtering (untyped)
  - Preprocessors
- Compositional Approaches
  - Language-based composition mechanisms (typed)
  - OOP, AOP, Templates
- Generative Approaches
  - Metamodel-based generation of components (typed)
  - MDD, C++ TMP, generators

Implementation Techniques: Goals

General
- Separation of concerns (SoC)
- Resource thriftiness

Operational
- Granularity
  Components should be fine-grained. Each artifact should either be mandatory or dedicated to a single feature only.
- Economy
  The use of memory/run-time expensive language features should be avoided as far as possible. Decide and bind as much as possible at generation time.
- Pluggability
  Changing the set of optional features should not require modifications in any other part of the implementation. Feature implements should be able to “integrate themselves”.
- Extensibility
  The same should hold for new optional features, which may be available in a future version of the product line.
AOP Mechanisms Demystified: "Obliviousness"

Scenario:
Optional feature component \( F_1 \) shall be integrated into SPL component \( PL \)

- With OOP:
  - \( PL \) has to call \( F_1 \) ~ \( PL \) has to know \( F_1 \)
  - control flows can only be established in the direction of knowledge

- With AOP:
  - \( F_1 \) can give advice to \( PL \) ~ \( F_1 \) has to may know \( PL \)
  - control flow is established opposite to the direction of knowledge
  - binding is inherently loose ~ silently missed, if \( PL \) does not exist
AOP Mechanisms Demystified: “Quantification”

**Scenario:**
(Nonfunctional) feature component $F_1$ shall be integrated into (optional) SPL components $PLC_{1...n}$

- With AOP:
  - binding is inherently loose $\leadsto$ may quantify over $n$ join points
  - possible by declarative pointcut concept (here: wildcard in match expression)

**Advice** inverses the direction in which control-flow relationships are established: $C$ calls $A \implies A$ advises $C$

- Aspects integrate themselves into the surrounding program $\leadsto$ "I make you call me"
- Surrounding program can be kept oblivious of the aspects $\leadsto$ advice-based binding as a means to integrate (optional) features

**Pointcuts** provide for an implicit quantification of this integration

- Applies to $0\ldots M \ldots n$ join points, depending on the pointcut expression $\leadsto$ Aspects can be kept oblivious of the surrounding program
- Thereby, advice-based binding is inherently loose $\leadsto$ advice-based binding as a means to integrate interacting features

    - Air Pressure
    - Wind Speed
  - Actuators:
    - Alarm
    - Display
    - PC Connection
  - Sensors
  - Actuators
  - Sensors
  - Actuators

- Configuration-related sensor and actuator sets
- Generic and nongeneric actuators
- using optional feature code
Weather and Sink are (almost) empty classes.

- Provide a lexical scope for sensor/actuator introductions
- Provide explicit join points (empty methods `measure()` / `process()`) that are invoked by the main loop, when measuring / processing should take place

- All further functionality is provided by the aspects!

A Sensor is implemented as a class with an accompanying Handling aspect
- Slices the sensor singleton into `Weather`
- Gives advice to `Weather::measure()` to invoke `Sensor::measure()`
- Slices an explicit join point `process_data(Sensor)` into Sink
- Gives advice to `Sink::process()` to invoke `process_data(Sensor)`
I4WeatherMon: AOP Sensor Integration

```cpp
class Weather {
    public:
    void measure() {} // empty implementation
};

class Sink {
    public:
    void process() {} // empty implementation
};

aspect PressureHandling {
    // Weather integration
    advice "Weather" : slice struct{
        Pressure _pressure; // introduce sensor instance (singleton)
    };
    advice execution( void Weather::measure() ) : before() {
        theWeather._pressure.measure(); // invoke sensor's measure()
    } // Sink integration
    advice "Sink" : slice struct {
        // introduce sensor-specific explicit join point for actuator aspects
    void process_data( const Pressure & ) {}
    };
    advice execution( void Sink::process() ) : after() {
        theSink.process_data( theWeather._pressure ); // trigger it
    }
};
```

I4WeatherMon: AOP Generic Actuator Integration

```cpp
aspect Display {
    // display each element of the weather data
    advice execution( "void Sink::process_data(%)" ) : before {} {
        typedef JoinPoint template Arg0::ReferredType Data;
        tjp->arg0()->str_val( val );
        print( Data::name(), val, Data::unit() );
    }
};
```

I4WeatherMon: AOP Solution Space

**Generic actuator integration**
A generic actuator (processes all sensors) is implemented by an aspect
- Gives advice to Sink::process() to execute processing pre-/post actions
- Gives generic advice to all overloads of Sink::process_data() to invoke each sensor (typed) in order to process its data via the generic str_val()
  ~ Generic actuator does not know the available / possible sensor types

**Nongeneric actuator integration**
A nongeneric actuator (processes some sensors) is implemented by an aspect
- Gives advice to Sink::process() to execute processing pre-/post actions
- Gives advice to selected overloads of Sink::process_data() to invoke them in order to process each sensors data via a sensor-specific interface
  ~ Nongeneric actuator has to know specific sensor types
I4WeatherMon: AOP Generic Actuator Integration

```java
aspect SNGConnection : protected PCConnection {
    UInt8 _p, _w, _t1, _t2; // weather record
    // let this aspect take a higher precedence than <Sensor>Handling
    advice process () : order ("SNGConnection", "<Handling>")
        : before () { /* init record */ }
    advice execution ("void Sink::process(const Weather&)")
        : after () { /* transmit record */ }
    // collect wind, pressure, temperature data by giving specific advice
    advice execution ("void Sink::process_data(...)") &&
        args (wind) : before (const Wind &wind) {
        _w = wind._w;
    }
    advice execution ("void Sink::process_data(...)") &&
        args (pressure) : before (const Pressure &pressure) {
        _p = pressure._p - 850;
    }
    advice execution ("void Sink::process_data(...)") &&
        args (temp) : before (const Temperature &temp) {
        _t1 = (UInt8)temp._t1;
        _t2 = temp._t2;
    }
};
```

I4WeatherMon: CPP vs. AOP – Footprint

AOP is as efficient as CPP-based configurability!

I4WeatherMon (AOP): Evaluation

**General**
- Separation of concerns (SoC)
- Resource thriftiness

**Operational**
- Granularity
  - Every component implements functionality of a single feature only.
- Economy
  - All control-flow bindings are established at compile time.
- Pluggability
  - Sensors and actuators integrate themselves by aspects.
- Extensibility
  - “Plug & Play” of sensor and actuator implementations.

CiAO: Motivation and Goals

Throughout the entire operating-system design cycle, we must be careful to separate policy decisions from implementation details (mechanisms). This separation allows maximum flexibility if policy decisions are to be changed later. 

Silberschatz, Gagne, and Galvin 2005: Operating System Concepts [8, p. 72]

- **Primary goal:** architectural configurability
  - configurability of even fundamental policies (synchronization, protection, interaction)
- **Secondary goal:** <the standards>
  - efficiency, configurability in general, portability
- **Approach:** aspect-aware operating system design
  - strict decoupling of policies and mechanisms in the implementation using aspects as the primary composition technique

CiAO: General Structure

- **Layered Architecture**
  - Interface layer (as/ciao)
  - System layer (os)
  - Hardware layer (hw)
- **Layers** → C++ namespaces
  - Potential join points for cross-layer transitions
  - Further refined by sublayers (os::krn, hw::irq)
  - Layers as a means of aspect-aware development → "visible transitions"

```c
// yields all hardware invocations from the system layer
preprocessor define OStoHW() = call("% hw::...::%(...)");
```

CiAO: Methodology: Principles of Aspect-Aware Development

- **Design Principles** → **Development Idioms**
  1. loose coupling by advice-based binding
  2. visible transitions by explicit join points
  3. minimal extensions by extension slices

A product line of aspect-oriented operating systems
- Implements OSEK VDX / AUTOSAR OS [1, 7]
- Fine-grained configurability of all system policies and abstractions
- Developed from scratch with AOP
Methodology: Principles of Aspect-Aware Development

The principle of loose coupling. Make sure that aspects can hook into all facets of the static and dynamic integration of system components. The binding of components, but also their instantiation (e.g., placement in a certain memory region) and the time and order of their initialization should all be established (or at least be influenceable) by aspects.

The principle of visible transitions. Make sure that aspects can hook into all control flows that run through the system. All control-flow transitions into, out of, and within the system should be influenceable by aspects. For this they have to be represented on the join-point level as statically evaluable, unambiguous join points.

The principle of minimal extensions. Make sure that aspects can extend all features provided by the system on a fine granularity. System components and system abstractions should be fine-grained, sparse, and extensible by aspects.

Methodology: Roles of Aspects and Classes

What to model as a class and what as an aspect?

- `<Thing>` is a class if — and only if — it is a distinguishable, instantiable concept of CiAO:
  - A system component, instantiated internally on behalf of CiAO
    - The Scheduler, the Alarm Manager, the OS control facility, ...
    - Hold and manage kernel state, singletons by definition
  - A system abstraction, instantiated as objects on behalf of the user
    - Task, Event, Resource, ...
    - In AUTOSAR OS: instantiated at compile time
  - Both are sparse — provide a minimal implementation only

- Otherwise `<thing>` is an aspect!

Methodology: Roles of Aspects and Classes (Cont’d)

Three idiomatic aspect roles

- **Extension aspects:** extend some system component or system abstraction by additional functionality.
- **Policy aspects:** “glue” otherwise unrelated system abstractions or components together to implement some CiAO kernel policy.
- **Upcall aspects:** bind behavior defined by higher layers to events produced in lower layers of the system.

Example: Mechanism Integration

```plaintext
Serial0
init()
sendBlock()

Sched
init()
ready()

<extension aspect>
Serial0Ext
exec("init")

<binding aspect>
Serial0_Init
exec("init")

Sched_Init
exec("init")

<slice>
Serial0Ext_Task
init

<slice>
Task_task
init

uses
ready
```

This might lead to additional functional dependencies

```
os::krn
hw::hal
```

visible transitions
by explicit join points

```
init()
```
Example: Mechanism Integration

<table>
<thead>
<tr>
<th>Serial0</th>
<th>Sched</th>
</tr>
</thead>
<tbody>
<tr>
<td>init()</td>
<td>init()</td>
</tr>
<tr>
<td>sendBlock()</td>
<td>ready()</td>
</tr>
</tbody>
</table>

-binding aspect-
Serial0_Init
exec("init")

-binding aspect-
Sched_Init
exec("init")

«extension aspect»
Serial0Ext
exec("init")

«binding aspect»
Serial0_Init
exec("init")

«binding aspect»
Sched_Init
exec("init")

«slice»
Serial0Ext_Task
Task_task
init()

Visible transitions by explicit join points

Binding aspects implement upcalls by advice-based bindings.

Example: Mechanism Integration

Cooperative Scheduling:

aspect Serial0Ext {
    advice execution( 'void hw::hal::init()' ) {
        order "Sched_Init", "Serial0_Init";
    };
}

Policy Integration

aspect Serial0Ext {
    advice execution( 'void hw::hal::init()' ) {
        order "Sched_Init", "Serial0_Init";
    };
}

This might lead to additional functional dependencies.

Example: Policy Integration

Cooperative Scheduling:

aspect Serial0Ext {
    advice execution( 'void hw::hal::init()' ) {
        order "Sched_Init", "Serial0_Init";
    };
}

Preemptive Scheduling:

aspect Serial0Ext {
    advice execution( 'void hw::hal::init()' ) {
        order "Sched_Init", "Serial0_Init";
    };
}
**Methodology: Explicit Join Points**

- Advice-based binding → availability of the "right" join points
  - for all semantically important transitions in the system
  - statically evaluable

- Fine-grained component structure → many implicit join points, but
  - amount and precise semantics often implementation dependent
  - aspects have to "know" → no obliviousness

- Important transitions not available for technical reasons as JPs
  - target code may be fragile (e.g., context switch) → must not be advised
  - target code may be written in assembly → transitions not visible as JPs

**Example: Policy Integration**

**Cooperative Scheduling:**
- `enterKernel()`
- `leaveKernel()`

**Preemptive Scheduling:**
- `reschedule()`
- `setNeedReschedule()`

- `enterKernel()`
- `leaveKernel()`

**Cooperative Scheduling:**
- `reschedule()`
- `setNeedReschedule()`

**Preemptive Scheduling:**
- `reschedule()`
- `setNeedReschedule()`

**Methodology: Explicit Join Points (Cont'd)**

- Solution: explicit join points
  - empty inline methods for the sole purpose that aspects can bind to them
  - explicitly triggered by components or other aspects
  - well defined semantics

- Upcall join points (U) represent system-internal events that are to be processed on a higher layer
  - exceptions, such as signals or interrupts
  - internal events, such as system initialization or entering of the idle state

- Transition join points (T) represent semantically important control-flow transitions inside the kernel
  - level transitions: user → kernel, user → interrupt
  - context transitions: threadA → threadB

Discussion: Aspect-Aware Development

By AAD CiAO achieves excellent properties [3–5]
- configurability and granularity even for fundamental kernel policies
- complete separation of concerns in the implementation

The approach has also been applied to other system software
- PUMA, the C/C++ transformation framework behind ac++ [9]
- CiAOIP, an aspect-oriented IP stack for embedded systems [2]

Issues: comprehensibility & tool support
- CiAO: aspect code/base code = 1/2.4
- missing or confusing error messages
- no support for weaving in template code
- no C0x support

Base code Aspect code

Agenda

4.1 AOP Mechanisms Under the Hood
4.2 Study: i4Weathermon AOP
4.3 CiAO
4.4 CiAO Results
4.5 Summary
4.6 References

Summary

Aspect-Aware Development exploits AOP mechanisms to achieve separation of concerns in configurable system software

- Advice inverses the direction in which control-flow relationships are established: C calls A \(\Rightarrow\) A advises C
- advice-based binding as a means to integrate (optional) features
- Pointcuts provide for an implicit quantification of this integration
- advice-based binding as a means to integrate interacting features

CiAO applies these concepts from the very beginning

- loose coupling by advice-based binding
- visible transitions by explicit join points
- minimal extensions by extension slices

The results are compelling

- configurability of even all fundamental system policies
- excellent granularity and footprint
