Mutex
Summary

Subject Matter
- discussion on abstract concepts as to unilateral and multilateral synchronisation, thus, partial and mutual exclusion
  - with the general semaphore as a measure that supports both
  - while the binary semaphore was/is intended to support the latter, only

Agenda
Preface
Fundamentals
Classification
Characteristics
Implementation
Data Structures
Functions
Mutex
Summary
discussion on abstract concepts as to unilateral and multilateral synchronisation, thus, partial and mutual exclusion
- with the general semaphore as a measure that supports both
- while the binary semaphore was/is intended to support the latter, only
- comprehensive differentiation of semaphore and mutex
- in terms of the mutual exclusion aspect only, computer science folklore is right in stating disparities between the general variant and a mutex
- but one have to be much more precise and argue with caution as far as the binary alternative is concerned

Hint (Methods v. Implementation/Entity)
A binary semaphore is a valid implementation of one of the many “mutex methods”, but not that restrictive as a “mutex entity” need to be.

elaboration of various implementation aspects regarding both types of semaphore as well as mutex as an entity
Concept for Cooperation and Communication

Definition (Binary Semaphore)

The semaphores are essentially non-negative integers; when only used to solve the mutual exclusion problem, the range of their values will even be restricted to “0” and “1”. [2, p. 28]
Concept for Cooperation and Communication

Definition (Binary Semaphore)

The semaphores are essentially non-negative integers; when only used to solve the mutual exclusion problem, the range of their values will even be restricted to “0” and “1”. [2, p. 28]

- jumping-off point for sleeping lock (Ger. Schlafsperrre, [8, p. 9]) and, in particular, mutex (abbr. mutual exclusion)

Definition (General Semaphore)

It is the merit of [...] C. S. Scholten to have demonstrated a considerable field of applicability for semaphores that can also take on larger values. [2, p. 28]

- also referred to as counting semaphore (Ger. zählender Semaphor)

Elementary Operations

- insensitive to the distinction between binary and general semaphore is the definition of two intrinsic primitives [1]:
  - P abbr. for (Hol.) prolaag; a.k.a. down, wait, or acquire, resp.
  - V abbr. for (Hol.) verhoog; a.k.a. up, signal, or release, resp.

Definition (Binary Semaphore)

The semaphores are essentially non-negative integers; when only used to solve the mutual exclusion problem, the range of their values will even be restricted to “0” and “1”. [2, p. 28]

- jumping-off point for sleeping lock (Ger. Schlafsperrre, [8, p. 9]) and, in particular, mutex (abbr. mutual exclusion)
insensitive to the distinction between binary and general semaphore is the definition of two intrinsic primitives [1]:

\[ P \text{ aabbr. for (Hol.) prolaag; a.k.a. down, wait, or acquire, resp.} \]
- decreases\(^1\) the value of the semaphore by 1:
  - i) iff the resulting value would be non-negative [2, p. 29]
  - ii) non-constraining [3, p. 345]
- blocks the process iff the value is or was, resp., 0 before decrease
  - blocking processes are put on a waitlist associated with each semaphore

\[ V \text{ aabbr. for (Hol.) verhoog; a.k.a. up, signal, or release, resp.} \]
- increases\(^1\) the value of the semaphore by 1
  - as the case may be, unblocks a process blocked on the semaphore
    - which process becomes unblocked is to be regarded as unspecified
- each primitive needs to be considered as an indivisible operation

\(^1\)This does not only mean subtraction or addition, resp., in arithmetical terms.
**Binary Semaphore**

- **Functional Dedication**
  - **Multilateral Synchronisation** [5, p. 15] of interacting processes
    - The critical section is considered as a non-preemptable reusable resource that needs to be allocated indivisibly to a process to be usable correctly.
    - In logical respect, the process having completed `P` on semaphore `S` is the only one being authorised to complete `V` on `S`.

```c
semaphore_t mutex = {1};
{
    P(&mutex);
    /* critical section */
    V(&mutex);
}
```

- Default value is, normally, 1
  - Block out only in the moment of a simultaneous process
  - Allow full bent, else

**Hint (Mutex (cf. p. 14/15))**

A mutex is a **binary semaphore** that incorporates an **explicit check for authorisation** to release a critical section in the moment of `V`.

- The critical section is considered as a non-preemptable reusable resource that needs to be allocated indivisibly to a process to be usable correctly.
- In logical respect, the process having completed `P` on semaphore `S` is the only one being authorised to complete `V` on `S`.

```c
semaphore_t mutex = {1};
{
    P(&mutex);
    /* critical section */
    V(&mutex);
}
```

- Default value is, normally, 1
  - Block out only in the moment of a simultaneous process
  - Allow full bent, else

- In case of a default value of 0
  - `V` must come before `P`
unilateral synchronisation [5, p. 15] of interacting processes
- used for availability control of entities of the following resource types:
  - a consumable resource in the form of any data of any number
  - a reusable resource of limited number, e.g., a data store (buffer), any device
- typical for, but not limited to, producer/consumer systems

also as noted previously [5, p. 15], this art of synchronisation means:
- logical coordination as indicated by a particular “role playing”
  - e.g., in order to proceed, a “data consumer” depends on the data to be made available by a “data producer”

conditional coordination as indicated by a condition for making progress
- e.g., in order to proceed, a “data producer” depends on the store available for data handling
unilateral synchronisation [5, p. 15] of interacting processes
- used for availability control of entities of the following resource types:
  - a consumable resource in the form of any data of any number
  - a reusable resource of limited number, e.g., a data store (buffer), any device
- typical for, but not limited to, producer/consumer systems

also as noted previously [5, p. 15], this art of synchronisation means:
logical
- coordination as indicated by a particular “role playing”
  - e.g., in order to proceed, a “data consumer” depends on the data to be made available by a “data producer”

conditional
- coordination as indicated by a condition for making progress
  - e.g., in order to proceed, a “data producer” depends on the store available for data handling
  - in the end, the data store will have to be deallocated and, thus, made available again by the “data consumer”

from this it follows that P and V applied to the same semaphore S must have to be accomplishable by different processes, normally which makes the big difference to a binary semaphore or mutex, resp.

Consumable Resource

```c
semaphore_t data = {0};
void producer() {
    for (;;) {
        /* data released */
        V(&data);
    }
}
void consumer() {
    for (;;) {
        P(&data);
        /* data acquired */
    }
}
```

- default value is 0
- P must block out only if there is no data
- V indicates more data
- calling sequence
  - V must be actable independent of P
  - in order to complete, P depends on V
  - beware of an overflow of the values margin

Reusable Resource

```c
semaphore_t store = {N};
void producer() {
    for (;;) {
        P(&store);
        /* store acquired */
    }
}
void consumer() {
    for (;;) {
        V(&store);
        /* store released */
    }
}
```

- default value is N ≥ 0
- P must block out only if there is no store
- V indicates more store
- calling sequence
  - V must be actable independent of P
  - in order to complete, P depends on V
  - beware of an overflow of the values margin

Reusable Resource

Availability Control

```c
semaphore_t store = {N};

void producer() {
    for (;;) {
        P(& store); /* store acquired */
    }
}

void consumer() {
    for (;;) {
        V(& store); /* store released */
    }
}
```

- default value is $N \geq 0$
- $P$ must block out only if there is no store
- $V$ indicates more store
- calling sequence
- $V$ must be actable independent of $P$
- in order to complete, $P$ depends on $V$
- beware of an overflow of the values margin
- as to interacting processes in the line of producer and consumer, the same applies as mentioned before: $\#V > \#P$
- in other cases: $\#V \leq \#P$, must be completed by the same process

Availability Control in Practice

Bounded Buffer

**Hint (Bounded Buffer)**

A means of managing an unlimited number of consumable resources on the basis of a limited number of reusable resources.

```c
semaphore_t data = {0}, store = {N}; /* N > 0 */

void producer() {
    for (;;) {
        P(& store); /* store acquired */
        V(& data); /* data released */
    }
}

void consumer() {
    for (;;) {
        P(& data); /* data acquired */
        V(& store); /* store released */
    }
}
```

- indisputable classic in cooperation and communication of processes
- simply a merge of the semaphore use pattern discussed as before
- transverse application of $P$ and $V$ to a pair of general semaphores
Hint
Checking **authorisation** for release of a critical section in that very moment is improper for a general semaphore, optional for a binary semaphore, and **may be** demanded for a mutex (cf. p. 15).

improper
- $P$ and $V$ on a **general semaphore** must be accomplishable in particular also by different processes
- this is prevented by a mutex entity—but not by a mutex

optional
- basically, a **binary semaphore** may be implemented by a general semaphore $S$, with $S \leq 1 \implies$ never a mutex entity
- values $S > 1$ must be prevented either by the use pattern or by the implementation of $P$ and $V$
Semaphore v. Mutex I

**Technical Level**

**Hint**

Checking **authorisation** for release of a critical section in that very moment is improper for a general semaphore, optional for a binary semaphore, and may be demanded for a mutex (cf. p. 15).

**demanded**
- A mutex entity ensures that the release of critical section CS will succeed only for the process having acquired CS.
- by extending a binary semaphore, P will have to record and V will have to check ownership of CS
- a mutex entity ensures that the release of critical section CS will succeed only for the process having acquired CS
- by extending a binary semaphore, P will have to record and V will have to check ownership of CS

**improper**
- P and V on a general semaphore must be accomplishable in particular also by different processes.
- this is prevented by a mutex entity—but not by a mutex
- this is prevented by a mutex entity—but not by a mutex

**optional**
- basically, a binary semaphore may be implemented by a general semaphore S, with S ≤ 1 ⇒ never a mutex entity
- values S > 1 must be prevented either by the use pattern or by the implementation of P and V
- values S > 1 must be prevented either by the use pattern or by the implementation of P and V
- if authorisation fails, the process attempting to release CS should be aborted
- if authorisation fails, the process attempting to release CS should be aborted

---

Semaphore v. Mutex II

**Conceptual Level**

**Hint (Computer Science Folklore)**

A semaphore can be released by any process.

---

Semaphore v. Mutex I

**Technical Level**

**Hint**

Checking **authorisation** for release of a critical section in that very moment is improper for a general semaphore, optional for a binary semaphore, and may be demanded for a mutex (cf. p. 15).

**demanded**
- A mutex entity ensures that the release of critical section CS will succeed only for the process having acquired CS.
- by extending a binary semaphore, P will have to record and V will have to check ownership of CS
- a mutex entity ensures that the release of critical section CS will succeed only for the process having acquired CS.
- by extending a binary semaphore, P will have to record and V will have to check ownership of CS

**improper**
- P and V on a general semaphore must be accomplishable in particular also by different processes.
- this is prevented by a mutex entity—but not by a mutex
- this is prevented by a mutex entity—but not by a mutex

**optional**

Instances of Process Instances

the standby position of a process within $P$ is passive, normally

Process Instances

A semaphore can be released by any process.

Semaphore v. Mutex II

Hint (Computer Science Folklore)

A semaphore can be released by any process.

Semaphore v. Mutex II

A semaphore can be released by any process.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.

Semaphore v. Mutex II

A mutex can be released only by the process having it acquired.
Hierarchic Placement

- the standby position of a process within $P$ is passive, normally
  - “blocks the” or “unblocks a”, resp. (cf. p. 8), process means rescheduling
  - if so, both may also entail context switching

---

Hierarchic Placement

- the standby position of a process within $P$ is passive, normally
  - “blocks the” or “unblocks a”, resp. (cf. p. 8), process means rescheduling
  - if so, both may also entail context switching—“may” because:
    - $P$ - if no further process is ready to run, the idle loop becomes active
      - in that case, the blocking process likewise may fade to the idle process
      - thus, doing without a dedicated idle-process instance and context switch

---

Hierarchic Placement

- the standby position of a process within $P$ is passive, normally
  - “blocks the” or “unblocks a”, resp. (cf. p. 8), process means rescheduling
  - if so, both may also entail context switching—“may” because:
    - $P$ - if no further process is ready to run, the idle loop becomes active
      - in that case, the blocking process likewise may fade to the idle process
      - thus, doing without a dedicated idle-process instance and context switch

---

Hierarchic Placement

- the standby position of a process within $P$ is passive, normally
  - “blocks the” or “unblocks a”, resp. (cf. p. 8), process means rescheduling
  - if so, both may also entail context switching—“may” because:
    - $V$ - if there is a waiting process, it will be set “ready to run” (cf. [9, p. 28])
      - in that case, priority violation$^3$ must be prevented (scheduling discipline!)
      - thus, the current process may defer to a prior-ranking one: context switch

---

3If at least one of the processes on the waitlist is of higher-priority than the current process but will not become “ready to run” or allocated the processor.
the standby position of a process within \( P \) is passive, normally
- “blocks the” or “unblocks a”, resp. (cf. p. 8), process means rescheduling
- if so, both may also entail context switching—“may” because:
  - \( P \) - if no further process is ready to run, the idle loop becomes active
    - in that case, the blocking process likewise may fade to the idle process
    - thus, doing without a dedicated idle-process instance and context switch
  - \( V \) - if there is a waiting process, it will be set “ready to run” (cf. [9, p. 28])
    - in that case, priority violation must be prevented (scheduling discipline!)
    - thus, the current process may defer to a prior-ranking one: context switch
- all this makes \( P \) and \( V \) programs of the operating system machine level
- \( P \) and \( V \) relies on process management of the operating system
- one have to put the current process asleep and get a sleeping process up

3If at least one of the processes on the waitlist is of higher-priority than the current process but will not become “ready to run” or allocated the processor.

## Waitlist Association

- in order to aid \( V \), processes blocked by \( P \) at a semaphore are entered on a waitlist in either logical or physical means
- if so, both may also entail context switching—“may” because:

## Process Instances

- the standby position of a process within \( P \) is passive, normally
- “blocks the” or “unblocks a”, resp. (cf. p. 8), process means rescheduling
- if so, both may also entail context switching—“may” because:
  - \( P \) - if no further process is ready to run, the idle loop becomes active
    - in that case, the blocking process likewise may fade to the idle process
    - thus, doing without a dedicated idle-process instance and context switch
  - \( V \) - if there is a waiting process, it will be set “ready to run” (cf. [9, p. 28])
    - in that case, priority violation must be prevented (scheduling discipline!)
    - thus, the current process may defer to a prior-ranking one: context switch
- all this makes \( P \) and \( V \) programs of the operating system machine level
- \( P \) and \( V \) relies on process management of the operating system
- one have to put the current process asleep and get a sleeping process up

### Logical
- to block, a blocked-on mark is stored in the process descriptor
- to unblock, a process-table walk looks for that mark
- constant \((P)\) and variable but bounded above \((V)\) run-time
- blocked-on mark is a “magic” address, no extra attributes
Waitlist Association

- in order to aid \( V \), processes blocked by \( P \) at a semaphore are entered on a waitlist in either logical or physical means
  - physical: to block, the process descriptor joins a queue data structure
  - to unblock, a process descriptor is removed from that structure
    - variable but bounded above \( (P) \) and constant \( (V) \) run-time
    - additional queue attribute of the semaphore data structure

- to block, a blocked-on mark is stored in the process descriptor
  - constant \( (P) \) and variable but bounded above \( (V) \) run-time

- to unblock, a process table walk looks for that mark
  - variable but bounded above \( (P) \) and constant \( (V) \) run-time
  - additional queue attribute of the semaphore data structure

- desirable is to have the waitlist queuing discipline in compliance with the process scheduling discipline: freedom of interference
  - a characteristic by means of which priority violation will be prevented
  - usually, this excludes straightforward queuing disciplines such as FCFS

Hint (Process-Table Walk—Conformance to Scheduling)

Part of the scheduler, lookup function to locate a process descriptor on the basis of the blocked-on mark as search key.

Indivisible Operation I

Rationale

- in the absence of simultaneous processes, the implementation of a semaphore could be as simple as follows:

```
void prolaag(semaphore_t *sema) {
    if (!claim(sema)) /* at the moment, unavailable */
        sleep(&sema->wand);
}
```

```
void verhoog(semaphore_t *sema) {
    if (unban(sema)) /* as from now, available */
        rouse(&sema->wand);
}
```

- whereat \( claim \) decreases and \( unban \) increases the value of the semaphore according to binary or general, resp., characteristic\(^4\)

\(^4\)The implementation of these helper functions will be revealed later.
Indivisible Operation I

Scope

- in the absence of simultaneous processes, the implementation of a semaphore could be as simple as follows:

```c
void pulaag(semaphore_t *sema) {
    if (!claim(sema)) /* at the moment, unavailable */
        sleep(&sema->wand);
}

void verhoog(semaphore_t *sema) {
    if (unban(sema)) /* as from now, available */
        rouse(&sema->wand);
}
```

- but, assuming that the presence of simultaneous processes is possible, this implementation shows a race condition \(
\sim\) lost wakeup

4 The implementation of these helper functions will be revealed later.

Indivisible Operation II

Scope

- \( P \) and \( V \) itself constitute a critical section, likewise, that must be protected in order to function correctly

```c
void pulaag(semaphore_t *sema) {
    atomic *sema = {
        if (!claim(sema))
            sleep(&sema->wand);
    }
}

void verhoog(semaphore_t *sema) {
    atomic *sema = {
        if (unban(sema))
            rouse(&sema->wand);
    }
}
```

- as a process will have to block inside a critical section, deregulation of protection is indispensable for the period the process is blocked

Deadlock Prevention

Provided that protection of the critical section on the \( P \) side is not deregulated, the \( V \) side will never complete and, thus, will never cause unblocking of a process:

- the right location for deregulation is \( sleep \)
- after the process was marked sleeping

- as a process will have to block inside a critical section, deregulation of protection is indispensable for the period the process is blocked
Shallows Implementation

- protection of the P/V pair against simultaneous processes sharing a semaphore follows either the blocking or non-blocking paradigm

**non-blocking**
- fall back on the elementary operations of the ISA level
- problem-specific construction of P and V
  $\leftarrow$ coming up as a case study in the context of LEC 10/11

Shallows Implementation

- more detailed analysis of the “atomic” version of P reveals another problem: overtaking of an aroused process
  - upon return from sleep a formerly blocked process may complete P by mistake, joining a process in the critical section to be protected by P
  - this is because completion of V also opens the door for any process, not only for a process having been blocked at the semaphore
  $\leftarrow$ if applicable, aroused processes have to retry claiming: if $\leftarrow$ while

\(^5\text{abbr. for first- or second-level interrupt handling, resp.}\)
Shallows

Implementation

- protection of the P/V pair against simultaneous processes sharing a semaphore follows either the blocking or non-blocking paradigm
  - **blocking**: inhibit FLIH, postpone SLIH, or lock process
  - problem-specific construction of an *enter/leave* pair
    - coming right up next in this lecture (cf. p. 22ff.)
  - **non-blocking**: fall back on the elementary operations of the ISA level
    - problem-specific construction of P and V
    - coming up as a case study in the context of LEC 10/11

- more detailed analysis of the “atomic” version of P reveals another problem: **overtaking** of an aroused process upon return from *sleep* a formerly blocked process may complete P by mistake, joining a process in the critical section to be protected by P
  - this is because completion of V also opens the door for any process, not only for a process having been blocked at the semaphore
  - if applicable, aroused processes have to **retry claiming**: if ↦ while

- not least, concurrency had to be constricted to no more than what is absolutely necessary: reflect on claim/sleep and unban/rouse

Outline

Preface

Fundamentals
  - Classification
  - Characteristics

Implementation
  - Data Structures
  - Functions
  - Mutex

Summary

Semaphore Data Type

```c
typedef volatile struct semaphore {
  int gate;  /* value: binary or general */
  wand_t wand;  /* protective shield */
} semaphore_t;
```

- purpose of “wand” (Ger. *Zauberstab*) is to **safeguard** the semaphore operations in various respect
  - protect P and V against simultaneous processes
  - give leeway for protection variants (cf. p. 20)
**Semaphore Data Type**

1. `typedef volatile struct semaphore {
   2. int gate;          /* value: binary or general */
   3. wand_t wand;       /* protective shield */
   4. } semaphore_t;

- purpose of “wand” (Ger. *Zauberstab*) is to **safeguard** the semaphore operations in various respect
  - i protect *P* and *V* against simultaneous processes
  - ii give leeway for protection variants (cf. p. 20)

- a wand that takes care of **mutual exclusion** techniques by means of locks [8], for example, could be the following:

1. `typedef volatile struct wand {
   2. lock_t clue;   /* protects *P* or *V*, resp. */
   3. event_t wait;  /* list of sleeping processes */
   4. } wand_t;

**P and V Safeguarded**

- **P and V Safeguarded**

```c
void prolaag(s semaphore_t *sema) {
  enter(&sema->wand);    /* avert overlapped *P* or *V* */
  lodge(sema);           /* raise claim to proceed */
  when (!avail(sema))    /* check for process delay */
    sleep(&sema->wand);  /* await wakeup signal */
  leave(&sema->wand);    /* allow *P* or *V* */
}
```

```c
void verhoog(s semaphore_t *sema) {
  enter(&sema->wand);    /* avert overlapped *P* or *V* */
  if (unban(sema))       /* release semaphore */
    rouse(&sema->wand);  /* cause wakeup signal */
  else                   /* no sleeping process... */
    leave(&sema->wand);  /* allow *P* or *V* */
}
```

**Exercise caution in the analysis of these program statements:**
void prolaag(semaphore_t *sema) {
  enter(&sema->wand);  /* avert overlapped P or V */
  lodge(sema);  /* raise claim to proceed */
  when (!avail(sema)) /* check for process delay */
    sleep(&sema->wand);  /* wait wakeup signal */
  leave(&sema->wand);  /* allow P or V */
}

void verhoog(semaphore_t *sema) {
  enter(&sema->wand);  /* avert overlapped P or V */
  if (unban(sema)) /* release semaphore */
    rouse(&sema->wand);  /* cause wakeup signal */
  else /* no sleeping process... */
    leave(&sema->wand);  /* allow P or V */
}

load/store-based implementation for a binary semaphore:

inline int lodge(semaphore_t *sema) {
  return 42;
}

inline bool avail(semaphore_t *sema) {
  return (sema->gate == 0) ? false : !(sema->gate = 0);
}

inline bool unban(semaphore_t *sema) {
  return (sema->gate = 1) && exist(&sema->wand);
}

if applicable, “when” takes care of overtaking processes
Acquire and Release Semaphore I

- load/store-based implementation for a binary semaphore:

```c
1. inline int lodge ( semaphore_t *sema ) {
   2.     return 42;
   3. }

4. inline bool avail ( semaphore_t *sema ) {
   5.     return (sema->gate == 0) ? false : !(sema->gate = 0);
   6. }

7. inline bool unban ( semaphore_t *sema ) {
   8.     return (sema->gate = 1) && exist(&sema->wand);
   9. }
```

- note that the semaphore value alone shows no indication of processes that potentially await a reveille (Ger. *Wecksignal*) as to this very semaphore
- only an explicit waitlist scan sheds light on that ~ `exist`

- also note the persisting sensitivity to simultaneous processes: `avail`
- use within a safeguarded program section is assumed...

Acquire and Release Semaphore II

- enumerator-based implementation for a general semaphore:

```c
1. inline int lodge ( semaphore_t *sema ) {
   2.     return sema->gate--;
   3. }

4. inline bool avail ( semaphore_t *sema ) {
   5.     return sema->gate >= 0;
   6. }

7. inline bool unban ( semaphore_t *sema ) {
   8.     return (sema->gate ++ < 0);
   9. }
```

- note that the absolute value of a “negative semaphore” gives the number of processes awaiting a reveille as to this very semaphore
- thus, there is no need for an explicit waitlist scan

© wosch  CS (WS 2016, LEC 7)  Implementation–Functions

© wosch  CS (WS 2016, LEC 7)  Implementation–Functions
in contrast to the shown general semaphore, a roused process has to **recheck his waiting condition** in $P$

**binary semaphore**
- overtaking possible
  - $gate = 1$ when a process aroused
  - rival process in $P$ causes $gate = 0$
  - is allowed to continue
  - aroused process has to wait
- **#define when while**
  - unsusceptible to erroneous rouse

**general semaphore**
- overtaking impossible
  - $gate \leq 0$ when a process aroused
  - rival process in $P$ causes $gate < 0$
  - will be forced to **sleep**
  - aroused process may proceed
- **#define when if**
  - susceptible to erroneous rouse

**binary semaphore**
- overtaking possible
  - $gate = 1$ when a process aroused
  - rival process in $P$ causes $gate = 0$
  - is allowed to continue
  - aroused process has to wait
- **#define when while**
  - unsusceptible to erroneous rouse

**Hint (erroneous rouse)**
_Caused by misuse of V or by forced and uncontrolled unblocking of a process that went to sleep in $P$. Both are programming errors: the former at (semaphore) application level, the latter at system level._
inline void sleep(wand_t *wand) {
    catch(&wand->wait); /* disclose process to V */
    leave(wand);        /* allow P or V */
    coast();            /* take a break */
    enter(wand);        /* apply for return to P */
}

inline void rouse(wand_t *wand) {
    leave(wand);        /* allow P or V */
    cause(&wand->wait); /* signal end of break */
}

---

**Special Process Management**

**Prevent Lost Wakeup**

1. **Constrain concurrency to no more than what is absolutely necessary:**
   2. Endorse interest of the current process of upcoming dormancy
   3. Soon dormant process was made known, deregulate P safeguard
   4. Transition to dormant state: rescheduling, context switch or idleness
   5. Apply for return to safeguarded P
   6. Dormant processes could be available, deregulate V safeguard
   7. Annulment of dormant state: rescheduling, context switch
General Process Management

*catch* exists in two variants, depending on the waitlist model (cf. p 17):
- i store of a blocked-on mark in the process descriptor or
- ii enqueue of the process descriptor into a queue data structure
- variant (i) writes to an own data structure of the current process, while variant (ii) manipulates a shared data structure
- signalises upcoming blocking (dormancy) of the registered process

*coast*
- blocks the current process, reschedules the processor, and either
  - performs a context switch or runs through the idle loop
  - manipulates a shared data structure (ready list)
  - performs the queuing function of the queue-based *catch*
- eventually returns when the blocking condition was nullified

*cause*
- unblocks the next registered process, if any, found by means of a
  - (i) process-table walk or (ii) dequeue operation
  - manipulates a shared data structure (ready list)
- if need be, the current process defers to a prior-ranking process

*Hint (Idle State (cf. p.16 and p.39))*

The last process blocked may find itself on the ready list. Same may happen to the “sleepy process” as *coast* runs deregulated to P/V.
Process States and State Transitions

ready ↔ running
blocked → ready
running → blocked

ready ↔ running
blocked → ready
running ↔ pending
pending → blocked

Semaphore Gatekeeper

as there is no single solution to protect $P$ and $V$ adequately, the wand attribute symbolises intention to application orientation

depending on the mode of operation or use case, the wand acts differently
assuming that processing elements are not multiplexed [7, p.5], then:

```c
inline void enter(wand_t *wand) {
    lock(&wand->clue);
}
inline void leave(wand_t *wand) {
    unlock(&wand->clue);
}
```

wand capability depends on the “type of exclusion” in relation to the required characteristics of the operating system machine level:

- partial  processor multiprocessing ~ interrupt control
- mutual  processor multiplication ~ process lock, see example above
Semaphore Gatekeeper

- as there is no single solution to protect $P$ and $V$ adequately, the wand attribute symbolises intention to application orientation
- depending on the mode of operation or use case, the wand acts differently
- assuming that processing elements are not multiplexed [7, p.5], then:

```c
inline void enter(wand_t *wand) {
  lock(&wand->clue);
}

inline void leave(wand_t *wand) {
  unlock(&wand->clue);
}
```

- wand capability depends on the “type of exclusion” in relation to the required characteristics of the operating system machine level:
  - partial
    - processor `multiplexing` ~ interrupt control
  - mutual
    - processor `multiplication` ~ process lock, see example above

- combination of both is optional, not mandatory, and problem-specific
  - depends on the degree of parallelism (a) allowed for by the application use case and (b) made possible by the ISA level

---

Specialisation of a Binary Semaphore

- given the concept of a binary semaphore, implementation of a `mutex` is straightforward and, absolutely, no black magic:
  - a mutex data structure is composed of two parts:
    - i a binary semaphore used to actually protect the critical section and
    - ii a handle that uniquely identifies the process having acquired the mutex
  - given such a structure, let the following two functions be defined:
    - `acquire` – performs the $P$ and registers the current process as owner
    - `release` – conditionally unregisters the owner and performs the $V$
      - in case of a wrong owner, the current process or kernel, resp., panics

```c
typedef volatile struct {
  semaphore_t sema; /* binary semaphore */
  process_t *link; /* owning process or 0 */
} mutex_t;
```

---

Mutex (cf. p. 14/15)

- at kernel level, the handle is the pointer to the process descriptor of the process instance. At user level, it is the process identification.

---

Semaphore Gatekeeper

- given the concept of a binary semaphore, implementation of a `mutex` is straightforward and, absolutely, no black magic:
  - a mutex data structure is composed of two parts:
    - i a binary semaphore used to actually protect the critical section and
    - ii a handle that uniquely identifies the process having acquired the mutex
  - given such a structure, let the following two functions be defined:
    - `acquire` – performs the $P$ and registers the current process as owner
    - `release` – conditionally unregisters the owner and performs the $V$
      - in case of a wrong owner, the current process or kernel, resp., panics

- a corresponding `data type` may be laid out as follows:

```c
typedef volatile struct mutex {
  semaphore_t sema; /* binary semaphore */
  process_t *link; /* owning process or 0 */
} mutex_t;
```

---

Mutex (cf. p. 14/15)

- at kernel level, the handle is the pointer to the process descriptor of the process instance. At user level, it is the process identification.
Acquire and Release Mutex

```c
extern void panic(char*) __attribute__((noreturn));

void acquire(mutex_t *mutex) {
    P(&mutex->sema); /* lockout */
    mutex->link = being(ONESELF); /* register owner */
}

void release(mutex_t *mutex) {
    if (mutex->link != being(ONESELF)) /* it's not me! */
        panic("unauthorised release of mutex");
    mutex->link = 0; /* deregister owner */
    V(&mutex->sema); /* unblock */
}
```

release of a mutex by an **unauthorised process** is a **serious matter**
- presumably, the non-sequential program contains a **software fault** (bug)
- returning an error code is no option, as one cannot rely on error checking

Outline

- Preface

- Mutex

Summary
Résumé

- fundamental concept for cooperation and communication
  - binary and general/counting semaphore, intrinsic primitives $P$ and $V$
  - correlation to unilateral and multilateral synchronisation
  - differentiation as to mutex (methods v. implementation/entity)

**Hint**

A binary semaphore is a valid implementation of one of the many "mutex methods", but not that restrictive as a "mutex entity" need to be.

- hierarchic placement at operating system machine level
- characteristics important in functional and non-functional terms
  - logical or physical waitlist, conformance to the scheduling discipline
  - deregulation of the protection of $P$ against simultaneous processes
  - further shallows such as overtaking of unblocked processes in $P$

**Hint**

Constrict concurrency to no more than what is absolutely necessary.

- not least, basic approaches and sketches of an implementation...
Résumé

fundamental concept for cooperation and communication
- binary and general/counting semaphore, intrinsic primitives \( P \) and \( V \)
- correlation to unilateral and multilateral synchronisation
- differentiation as to mutex (methods \( v. \) implementation/entity):

**Hint**

A **binary semaphore** is a valid implementation of one of the many “mutex methods”, but not that restrictive as a “mutex entity” need to be.

- hierarchic placement at operating system machine level
- characteristics important in functional and non-functional terms
  - logical or physical waitlist, conformance to the scheduling discipline
  - deregulation of the protection of \( P \) against simultaneous processes
  - further shallows such as overtaking of unblocked processes in \( P \):

**Hint**

Constrict concurrency to no more than what is absolutely necessary.

Extent of Critical Section

Binary Semaphore devoid of Waitlist

let the sequence of instructions within \( P \) be as follows:

1. move 16(%esp), %edi
2. leal 4(%edi), %esi
3. jmp LBB0_2

LBB0_1:
4. movl _life, %eax
5. movl %esi, 4(%eax)
6. movl %esi, (%esp)
7. calll _unlock
8. calll _coast

LBB0_2:
9. movl %esi, (%esp)
10. calll _lock
11. cmpl $0, (%edi)
12. je LBB0_1
13. movl $1, (%edi)
14. movl %esi, (%esp)
15. calll _unlock

...
Semaphore v. Mutex III

Commonalities and differences as to their possible **internal states**.

- **general semaphore** $S_g$:
  - **positive**: $N > 0$ processes will complete $P(S_g)$ without blocking
  - **zero**: $P(S_g)$ will block the running process on the waitlist of $S_g$
  - **negative**: $P(S_g)$ will block the running process on the waitlist of $S_g$
    - $|N|$ processes are blocked on the waitlist of $S_g$

- **binary semaphore** $S_b$:
  - **not taken**: exactly one process will complete $P(S_b)$ without blocking
    - the very process becomes **logical owner** of $S_b$
  - **taken**: $P(S_b)$ will block the running process on the waitlist of $S_b$
    - $V(S_b)$ should be performed only by the logical owner of $S_b$

- **mutex entity** $M$: let $A$ be **acquire** and let $R$ be **release**
  - **not owned**: exactly one process will complete $A(M)$ without blocking
    - the very process becomes **physical owner** of $M$
  - **owned**: $A(M)$ will block the running process on the waitlist of $M$
    - $R(M)$ can succeed only for the physical owner of $M$

---

Idle State

- **principle pattern** of a scheduler function to block a process
  - called by **coast** (cf. p.27) and other functions to pause computation

```c
void block() {
    process_t *next, *self = being(ONESELF);
    while (!(next = elect(hoard(READY))))
        relax(); /* no ready to run... */
    if (next != self) {
        /* must relinquish */
        self->state = BLOCKED; /* vacate processor */
        seize(next); /* resume elected */
    }
    self->state = RUNNING; /* occupy processor */
}
```

- **choose next process** to be dispatched to the processor
- **ready list** is empty, so the running process fades to the idle process
- as the case may be, the running process may be allowed to continue:
  - i the idle/running process found itself ready-to-run on the ready list
  - ii the running process, sent to sleep due to $P$, was roused due to $V$ (p.27)
